Abstract

Toxoplasmosis is a zoonotic disease caused by infection with the parasite called *Toxoplasma gondii* (*T. gondii*). The health and social impacts of the infection are enormous, including miscarriage, hydrocephalus, blindness, and mental retardation. The occurrence of toxoplasmosis in maternal women cannot be separated from cats around their houses. This study aimed to determine the seroprevalence of the parasite in cats found in the human carriers residences and identify the risk factors of toxoplasmosis in maternal women in Badung District, Bali Province, Indonesia. A total of 80 cat serum samples were obtained from two residential groups, 40 from the housing where the maternal women were infected and another 40 from where there were no identified sufferers of the disease. All the samples were examined using the enzyme-linked immunosorbent assay (ELISA) method to detect the presence of antibodies *T. gondii* in feral cat serum. The results showed that 47.5% of the examined subjects had the said antibodies. As much as 65% came from housing with cases of toxoplasmosis in maternal mothers, and 30% came from residences with none. The presence of feral cats is a major risk factor for the transmission of *T. gondii* to humans.

Keywords: cats, maternal women, risk factor, *Toxoplasma gondii*, toxoplasmosis

Introduction

Human toxoplasmosis is an emerging disease in both developed and developing countries with a varying prevalence.1-3 In Indonesia, this disease has been reported in various regions with seroprevalences ranging from 3.1% to 64%.4-12 In Bali, Sukaryawati,13 reported a 41.8% of seroprevalence in Mengwi Subdistrict, Badung District, and a recent study found a rate of 10.9% in pregnant women.10 The previous study on toxoplasmosis among blood donors in Bali showed a seroprevalence of 35.9%, while among the women blood donors were about 63.9%. Furthermore, the seroprevalence of toxoplasmosis in blood donors in Badung District was 29.2%; in Tabanan District, 38.6%; in Gianyar District, 25.0%; while in Denpasar City, Klungkung City, and Bangli District were 41.1%, 25.0%, and 8.31%, respectively. In each district of Bali Province, the seroprevalence of toxoplasmosis among women was reported: Badung District, 33.3%; Tabanan District, 66.5%; Gianyar District, 82.5%; while in Denpasar City, Klungkung City, and Bangli District was 71.1%, 81.5%, and 16.7%, respectively.14 Another study determined the seropreva-

ience of human toxoplasmosis in the Gianyar District to be 56.7%.15 In Bali Province, the seroprevalence for toxoplasmosis in animals, was also reported to be 50% in cats,16 5.26% in pigs,17 and 24.8% in local chickens.18

Several epidemiological studies indicated that the presence of a cat in residence or premises increases the risk of *T. gondii* infection, especially in pregnant women.19-22 The presence of cats will pollute the surrounding environment with feces containing oocysts of the parasite.23 As reported before, the areas where there are many of the aforementioned animals roaming in the streets, markets, and public places are contaminated by the oocysts.24,25 In addition to cats which are widely highlighted as a risk factor for toxoplasmosis, eating habits increase the risk of infection with *T. gondii* in humans.26 In Europe, for instance, more infections occur as a result of consuming meat and its processed products that have not been completely cooked,27 while in Brazil, most of the infections are due to ingestion of oocysts that contaminate drinking water or vegetables.28,29 Similar findings are also reported in several developing countries.30 In Indonesia, including Bali Province, it has been

reported that eating habits, such as the consumption of lawar, a kind of food made from raw meat mixed with some vegetables and undercooked satay, determine the occurrence of these parasitic infections.\(^6\),10,11,31,32

The concept of one health/eco-health focuses on three main aspects in epidemiology related to toxoplasmosis,\(^11\) namely; the humans, the animals that serve as definitive hosts (such as cats), and other warm-blooded organisms that serve as intermediate hosts, as well as the environment contaminated by infective oocysts from \textit{T. gondii}. Extant studies on the epidemiology of toxoplasmosis have only focused on one aspect. However, this study focused on three; the socio-demography of maternal women, the presence of cats as a source of infection, and the environment contaminated by the feces containing \textit{T. gondii} oocysts.\(^16\) This type of epidemiological study, especially in maternal women, which focuses on the three aforementioned aspects, has never been carried out. In addition, studies conducted on toxoplasmosis thus far in this category of individuals and its relationship with the presence of cats as a source of transmission have never been investigated on the status of the associated infection by serological, coproscopic, and molecular tests.

**Method**

This study used a case-control approach while the maternal women checked their pregnancy at a clinic or laboratory in Denpasar City, Bali Province. All the positive maternal women recorded in the laboratory were used as a sampling frame, then they were selected using a simple random sampling. Those that were randomly selected as samples were divided into two groups; those that were positive for toxoplasmosis serologically (cases) and those that were negative (control). The control group was selected from the nearest neighbors of the selected sample cases. In addition, a study was carried out on cats living with maternal mothers in Bali Province. Fecal samples were examined by concentration flotation techniques to investigate the oocysts of the parasite.\(^16\) The ELISA test was conducted on the serum samples. The presence of specific gamma immunoglobulin (IgG) antibodies against \textit{T. gondii} was determined separately by the use of indirect ELISA tests (Human-GmbH, Wiesbaden, Germany [Ger]).\(^34\)

The statistics were conducted by calculating the odds ratio (OR) value of each examined risk factor, and by bivariate analysis using the Chi-square test (\(\chi^2\)) to evaluate the significance of the association between the toxoplasmosis incidents on maternal women and the risk factor to obtain the \(\chi^2\), 95% confidence interval (CI), and OR values. The statistically significant risk factors were related to the toxoplasmosis incidents on the maternal women (p-value<0.25), followed by the multivariate analysis using the logistic regression test to obtain the OR and p-value<0.05 values, as well as the final model of the regression. The discovered molecule-based data were used to strengthen the result of the microscopic test to ensure that the oocyst found belonged to the \textit{T. gondii}. All the statistical analysis was conducted with the Stata version 12.1 software.

**Results**

Table 1 shows the proportion and seroprevalence of \textit{T. gondii} in cats living with maternal mothers in Bali Province. The authors found that 17.5% of cats were infected by \textit{T. gondii}; 30% were from housing with cases...
of toxoplasmosis in maternal mothers, and 5% were from residences with none. While the seroprevalence of *T. gondii* in cats was found to be 47%, out of which 65% occurred in the case study area and 35% in the control area. In Figure 1, it was found that the oocysts of *T. gondii* were in two forms, e.g., sporulated and un-sporulated oocysts.

Table 2 shows the sociodemographic characteristics of the respondents. In the case group, most of them (60.0%) were over 31 years old. While in control, most of them (60.0%) were below that age. When considered based on the level of education, most (50.0%) of the respondents in the case group attained high school, while most of the respondents (52.5%) in the control group went to college. From the occupational point of view, most (32.5%) were housewives. When observed from the history of miscarriage, most of the respondents in the case group (80.0%) admitted having had one, and most of the control (82.5%) claimed to have had none. From the status of antenatal care, most of them (72.5%) in the case group were examined by a doctor, while in the control group, most (62.5%) of them also received a similar level of care in their pregnancy.

Table 3 shows the behaviors and habits at risk of toxoplasma infection in maternal cases and control groups. The result indicated that out of 80 maternal women studied, 52.5% had frequent contact with the ground in their daily activities. In contrast, the remaining 47.5% stated that they never or rarely had such contact.

like bathing, washing, cooking, and others was obtained from the regional drinking water company (tap), wells, rivers, and springs. The four sources were grouped into two, namely, tap and non-tap sources. As much as 51.25% of the water used by the respondents was from non-tap (wells, rivers, springs) sources, and the remaining 48.75% was from the tap.

Toxoplasma sp. infection is avoidable when the food or water consumed is free of T. gondii oocyst contamination. This is achievable with the habit of washing meat, vegetables, or other foodstuffs before cooking or eating them. Among the maternal women interviewed, 96.25% stated that they always wash meat, vegetables, or other food ingredients before cooking or consumption, while the remaining 3.75% have the habit of not washing them.

Table 4 shows the presence of cats in or around the house of maternal women. The presence of cats at home or around the house of the subjects in the case group indicated that 80% were feral or not kept, and it was observed to be 90% in the control group. The statistical analysis showed no significant relationship between raising cats and the incidence of toxoplasmosis in maternal women (p-value = 0.499 > \( \alpha = 0.05 \)). Most of the cats residing in and around their houses were under one year old, which was 75% in the case group and 72.5% in the control group. Statistically, the relationship between cat age and the incidence of toxoplasmosis in maternal women was not significant (p-value = 0.799 > \( \alpha = 0.05 \)).

In this study, information on handling cat feces in or around the house was also extracted; as many as 72.5% of them from the case group stated that they did not usually clean the feces. Also, 70% of maternal women from the control group stated the same behavior. The results of this study statistically did not show a significant relationship between handling cat feces and the incidence of toxoplasmosis (p-value = 0.81 > \( \alpha = 0.05 \)).

Table 5 shows the independent variables that affected the incidence of toxoplasmosis in maternal women and is the final logistic regression model. The results indicated that the level of maternal education, the presence of toxoplasmosis-positive cats evaluated by serological tests, and their feces by coproscopy, which contained T. gondii oocysts that contaminated the environment were risk factors for the incidence of toxoplasmosis in maternal women in Bali Province.

Discussion

This study revealed that a difference exists between the subjects' groups based on the age of maternal women. Several studies on the relationship between age and the incidence of toxoplasmosis have been reported with various results. In Thailand, it has been reported that the highest prevalence of toxoplasmosis in pregnant women was between 20–40 years of age.\(^{35}\) Another study conducted in Korea and China by Rai, et al., discovered that the highest prevalence occurred in the age group over 40 years.
years. Recent report in the Wasit Province of Iraq gave the highest infection rate as 19.9% in women aged 20–29 years, but with no significant difference between the ages studied. The results of this study and two others in Asia showed that the incidence of toxoplasmosis in pregnant women was not influenced by age. This agreed with Fromont, et al., which stated that individuals are at risk of contracting toxoplasmosis throughout their lifetime. According to these findings, each age group had a high risk of toxoplasmosis infection. Therefore, early detection, prevention, and treatment programs should target all age groups.

The statistical test results in the education level variable revealed that the value of OR = 3.4, which means that maternal women who attended only elementary and junior high schools were at risk of contracting toxoplasmosis. This was about 3.4 times greater than those with sufficient education (senior high school and college graduates). The results of this study were in line with that conducted by Ferreira, et al., in which a low level of education greatly influenced the incidence of toxoplasmosis in residents of a Brazilian Amazonian village. According to the study of Lopes, et al., a relationship exists between education level and economic status on the incidence of toxoplasmosis in pregnant women in Parana, Brazil. However, this result is in contrast to that obtained from the study by Kapperud, et al., which reported that the level of education did not significantly influence (OR = 1.8, p-value = 0.08) the incidence of toxoplasmosis in pregnant women in Norway. This may be influenced by many factors, including climate, the population density of cats—especially the feral ones, sociocultural status, level of education, knowledge, and healthy living behaviors. Since a low educational level contributes to an increased likelihood of being infected by toxoplasmosis, health promotion programs must aim at targeting those who have low educational levels. Their low educational levels notwithstanding, adequate knowledge related to risk and prevention behavior of toxoplasmosis transmission could reduce the risk of toxoplasmosis infections.

Miscarriage is one of the symptoms of *T. gondii* infection in pregnant women, therefore, the history of this occurrence was also analyzed in this study. Generally, the results obtained indicated that 48.75% of all the participating maternal women had experienced miscarriages. In the group of those infected with *T. gondii* (cases), 80% had a positive history of a miscarriage, while in the uninfected group (control), 10.75% had such experience. This data statistically shows a very significant difference (p-value = 0.003) with an OR of 18.8, which means that those infected with *T. gondii* have nearly 19 times the risk of miscarriage compared to the uninfected ones. This study’s results were much higher than those obtained from a study conducted in Sudan by Mohamed, et al., who discovered that pregnant women who contracted toxoplasmosis had a three times greater risk of experiencing miscarriage than those who were not infected. Another study by Khurana, et al., in Sri Lanka reported that miscarriage in pregnant women was caused by *T. gondii* infection. Ekanayake and Kurukulasuriya reported that 34% to 58.5% of pregnant women in Sri Lanka that were infected experienced spontaneous abortion. Since miscarriage occurred due to toxoplasmosis infection; health programs should promote the early detection in women, especially prior to conception. A detection conducted in late pregnancy could increase the likelihood of a miscarriage and maternal problems. Therefore, toxoplasmosis screening among all women of reproductive age is an essential priority in health programs.

The habit of washing meat and vegetables before they are processed has a significant role in preventing toxoplasmosis in humans, especially when consuming raw items. The results obtained in this study indicated that 3.75% of the respondents were still in the habit of not washing before cooking. Kapperud, et al., agree that consuming raw vegetables and fruits that are dirty (not washed) causes a higher contraction rate of toxoplasmosis infection. Various studies on habit or lifestyle have been reported as risk factors for *T. gondii* infection in humans, but the reports vary by region or country. This is due to the different modes of transmission of the disease, as most toxoplasmosis occurrences in urban areas in Brazil occur due to ingestion of oocysts that contaminate drinking water or vegetables. Similar observations have been reported in several other developing countries such as Turkey, Armenia, and Colombia. In contrast, the mode of transmission of toxoplasmosis in humans in developed countries such as in Europe is mostly by consuming meat or processed products that have not been cooked completely. Based on these findings, it is essential to promote hygienic behavior among members of the society regardless of their location in urban or rural areas, by publicizing prevention messages, especially those relating to food processing and storage, and making adequate clean water accessible along with prioritizing the provision of better sanitation facilities in the society.

As many as 85% of the respondents have both domestic and feral cats around their houses. Cat gender was balanced between the groups: 56.25% female and 43.75% male, and most of them were feral or not adequately maintained. These conditions are expected to continuously increase the population of stray cats in Bali Province, a medium for spreading toxoplasmosis. Judging from the cats’ ages, 73.75% of them were less than one year old and, when infected with *T. gondii*, there
is a likelihood of a broader and faster spread in Bali Province. In addition, cats under one year of age do not have antibodies against the parasite. Thus, they are easily infected. Tenter, et al., stated that cats less than one-year-old produce *T. gondii* oocysts in greater numbers than adult cats. Kapperud, et al., supports this observation by finding that pregnant women who have daily contact with kittens aged less than one year old are four times more likely to contract toxoplasmosis than those who do not. The existence of cats among humans is inevitable, so it is essential to prevent contamination from cat feces by controlling the population of cats. In collaboration with the local authority, communities could sterilize the cats to reduce their population. Promoting healthy pet ownership could also be an empowering approach by communities to prevent the spread of toxoplasmosis infections.

This study provided an in-depth understanding of the risk factors of toxoplasmosis infection among maternal women in Bali Province. It is noteworthy that the issue of toxoplasmosis has not been well explored in Bali Province. Therefore, this study provided recent updates relating to the status of zoonosis in Bali Province, which has hitherto been neglected but can potentially cause serious public health impacts. Although this study better comprehends the seroprevalence and risk factors of toxoplasmosis among maternal women, it can still not depict the situation in other parts of Bali Province. Furthermore, this study’s sample size was small; thus, it is essential to conduct further study targeting a broader population, such as women of reproductive age from other parts of Bali Province.

**Conclusion**

The proportion of oocysts and the seroprevalence of *T. gondii* in cats was 17.5% and 47.5%, respectively. A low education level and the presence of toxoplasmosis in cat feces determined by both serological and microscopic tests increase the risk of toxoplasmosis infection among pregnant women in Bali Province. In response to these findings, health prevention programs should target individuals with low educational levels and promote cleanliness and hygienic behavior. Moreover, encouraging women of reproductive age to participate in toxoplasmosis screening programs is also essential, especially to prevent the risk of miscarriage and the maternal health problems that may occur. In addition, controlling the cat population and providing better sanitation access is essential to prevent the transmission of toxoplasmosis.

**SCOPE**

Focus of Kesmas: National Public Health Journal is on public health as discipline and practices related to preventive and promotive measures to enhance health of the public through scientific approach applying variety of technique. This focus includes area and scope such as biostatistics, epidemiology, health education and promotion, health policy and administration, environmental health, public health nutrition, sexual and reproductive health, and occupational health and safety. The journal employs peer-review.
mechanism where each submitted article should be anonymously reviewed by expert peers appointed by the editor. Articles published in this journal could be in form of original article and invited review article.

Dear Scimago Team,

I am an editor in chief of this journal. Thank you for your answer to the question about our journal; I shall give them information on everything they ask. I have one question. The Scopus coverage years of this journal are from 2016 to the Present but in Scimago the coverage only for 2016-2019. Could you give a reason, because I have many questions from the writers concerning this case?

Thank You.
Regards,
Dewi Susanna

reply

Melanie Ortiz 12 months ago

Dear Dewi,

Thank you for contacting us. SJR is a portal with scientometric indicators of journals indexed in Scopus. All the metadata (Title, ISSN, Publisher, Coverage, Country, etc.) have been provided by Scopus /Elsevier in their latest update (April 2020) and SCImago doesn’t have the authority over these data which are property of Scopus/Elsevier. Keep also in mind that the SJR (Scientific Journal Rankings) is an indicator that Scopus calculates and it is not the same as Scopus coverage years. The SJR ranks are updated annually. If you would like to correct any of the data, please contact Scopus/Elsevier directly.

Thank you.

Sincerely,

Melanie Ortiz
mind that the SJR is a static image of Scopus, the update is made only one time per year and changes regarding the coverage can not be done until the following update. Sometimes there is inconsistency between the data observed in the Scopus database and the data that they sent to us. Despite the inconsistency we can not make changes concerning some metadata as the coverage.

Best Regards, SCImago Team

Mohammad Nazmul Hoq 1 year ago

Dear Hamdah,
thank you for contacting us.
Unfortunately, we cannot help you with your request, we suggest you visit the journal’s homepage or contact the journal’s editorial staff , so they could inform you more deeply.
Best Regards, SCImago Team

Nazmul Hoq 1 year ago
Dear Melanie Ortiz
Is Kesmas: National Public Health Journal index in scopus?

Is Scimago consider the journal for ranking which indexed in scopus?

Thanks
reply

Melanie Ortiz 1 year ago
Dear Nazmul,
Thank you very much for your comment.
All the metadata have been provided by Scopus /Elsevier in their last update sent to SCImago, including the Coverage’s period data. The SJR for 2019 was released on 11 June 2020. We suggest you consult the Scopus database directly to see the current index
status as SJR is a static image of Scopus, which is changing every day.
Best Regards, SCImago Team
